

## Wallet – Enhancement of EMV Card Data

EMV Primary Account Number (PAN) nnnnnnnnnnnnnnnnnnnn

“Decomposed” Counterpart

|                    |                                        |                                                                                                                                                                                                                      |
|--------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account ID         | <span>Account Identifier String</span> | Payment network compatible account identifier.<br>Examples: <b>FR7630004003200001019471656</b> for a French IBAN and <b>4111111111111111</b> for a VISA card.                                                        |
| Payment Network ID | <span>URL or Specific String</span>    | Payment network identifier.<br>Examples: <b>https://banknet2.org</b> for a hypothetical bank network and <b>visa</b> for the VISA network.                                                                           |
| Issuer ID          | <span>URL or Host Name</span>          | URL to an issuer endpoint like: <b>https://mybank.fr/payment</b> .<br>This solution eliminates Account ID to issuer URL lookup databases. An even better solution would be the <b>.well-known</b> extension concept. |

The variables above are the only elements that protocol-wise separate user authorizations for different payment networks, while from the user’s perspective, only card images differ.
